Site Selection

Modelling

Volumes

Injection

Monitoring

# Nomenclature/Units/Facts

- ▶ 1 car emits 4.6 T CO<sub>2</sub> per year
- ▶ 1 Ton CO<sub>2</sub> = 556.3 m<sup>3</sup> = 20 MSCF
- ▶ 3 billion tones of CO<sub>2</sub> emissions in 2020
- ▶ G20 countries produce 80% of CO<sub>2</sub> emissions
- ▶ Ultimate goal is the development of green energy sources, effective measures are required in the short term
- ▶ CCS - Carbon Capture and Storage
- ▶ CCUS - Carbon Capture Utilization an Storage - not in public favour
- ▶ EOR - Enhanced Oil Recovery

Mitigation of  
Global  
Warming

Monitoring

# CO2 Sequestration: Recap

- ▶ Natural CO2 sequestration into carbon sinks: Forests, soils and oceans
- ▶ Induced CO2 sequestration into geological structures: Depleted reservoirs, aquifers (CCS) and EOR processes (CCUS).
- ▶ Both CO2 Sequestration processes reduce CO2 emissions in the planet - reduce green house effects
  - ▶ CCS in Europe: mostly offshore
  - ▶ CCUS: Make EOR projects economically attractive and contribute to sustainability

# CCS Projects in the World

Project/Country/Year	Storage	Injection	Comments
Sleipner, Norway, 1996	Aquifer (sand)	0.9 MMT/Yr; 16.5 MMT until 2015	Low cost of separating CO2 from produced gases & tax reduction
Frio Pilot, USA, 2002	Aquifer	1600 T, for 10 days	Monitor plume to validate models
Cranfield, ISA, 2009	Depleted oil field	Cumulative 2015 = 5 MMT	5 MMT monitored; validate models
Decatur, USA, 2011	Aquifer (sand)	1000 T/daily over 3 yrs	CO2 from industrial processing Ethanol plant; completed in 2014
Ketzin, Germany, 2004	Aquifer(sand)	630 m aquifer	pilot terminated in 2017
Otway, Australia, 2008	Depleted gas field	150 T daily	2 Km TVD
Gorgon, Australia, 2012	Aquifer	2000 m below res.	14% CO2 from producing gas field
Salah, Algeria, 2004	aquifer in field	1.2 MMT/Yr,	10% CO2 from produced gas

# Largest CCUS (CO<sub>2</sub>-EOR) Operators in USA

- ▶ In US 80%+ of CO<sub>2</sub> for EOR projects comes from natural sources; Mississippi, CO<sub>2</sub> purchases cost \$5-\$12/Ton
- ▶ 1<sup>st</sup>, 2<sup>nd</sup> and 3<sup>rd</sup> Largest CO<sub>2</sub> operators in US (Oxy, Kinder Morgan, Denbury):
  - ▶ Oxy's high CO<sub>2</sub> utilization factor - they recycle their CO<sub>2</sub> 40x to get the NET utilization factor down.
  - ▶ Permian Basin, miscible CO<sub>2</sub> floods, gross total gas injected utilization 7-20 Mscf/BO and net utilization of 3-15 Mscf/BO; net being total injected gas less recycle injected gas.
  - ▶ Mississippi, utilizations much higher 20-35 Mscf/BO with net 10-20 Mscf/BO
  - ▶ To go for CO<sub>2</sub> EOR projects with high utilization factor, we need cheap CO<sub>2</sub> and tax incentives.
- ▶ CO<sub>2</sub>-EOR in Weyburn fractured carbonate, Canada, 2000, 320 km CO<sub>2</sub> pipeline - 130 MMbbls incremental oil.
- ▶ CO<sub>2</sub> tax in Europe is 40 Euro/Ton

# Geological Considerations for CO<sub>2</sub> storage

- ▶ Geological storage considerations:
  - ▶ Structure & Volumes
    - ▶ Depleted oil/gas reservoirs
    - ▶ Aquifers
    - ▶ Coal beds
    - ▶ Salt caverns
  - ▶ Cap rock extension and integrity
  - ▶ Depth (compression requirements)
  - ▶ Surface constraints
  - ▶ Distance from source

# Site Selection - Depleted Reservoirs - Pros & Cons

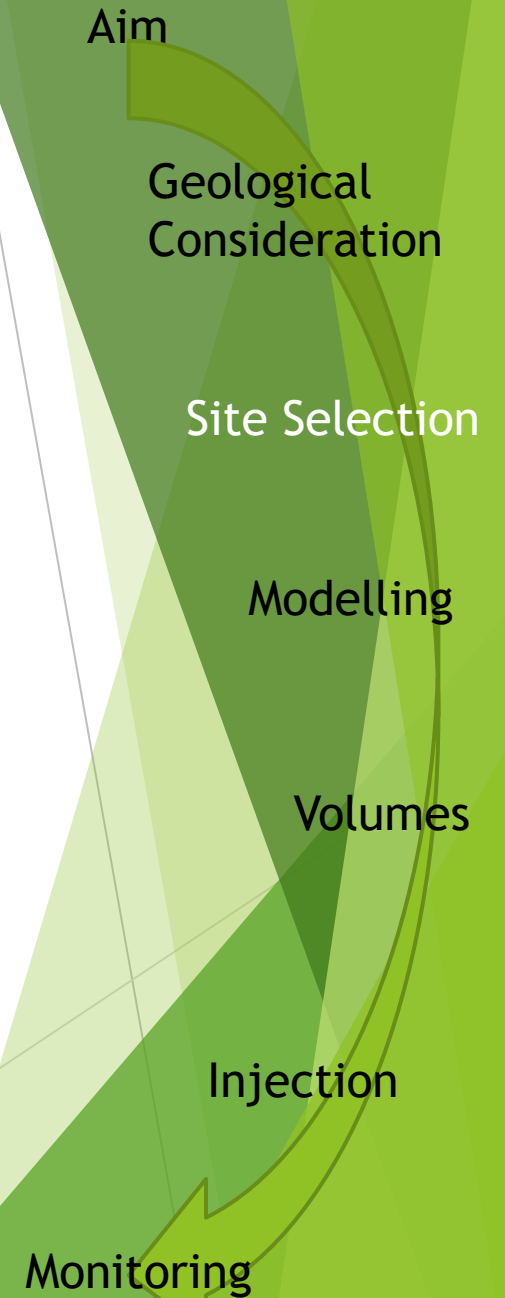

## ▶ Depleted Reservoirs

### ▶ Pros

- ▶ Geological and petrophysical information is favourable
- ▶ Volumes are well known
- ▶ Cap rock integrity has been proven
  - ▶ Geological containment demonstrated over geological time
- ▶ Existing wells could be used for monitoring

### ▶ Cons

- ▶ Well Integrity Issues; can we P&A old wells safely ? OH vs CH completions ?
- ▶ Completion materials:
  - ▶ CRA; Carbon steel controlled hardness F22 and corrosion inhibitors to deal with H2S cracking corrosion - if injected sour gas with 5% H2S and 5% CO2
  - ▶ Cladded material or made of Nickel alloy 28.
- ▶ Cement quality - cross-flow behing pipe

# Site Selection - Aquifers - Pros & Cons

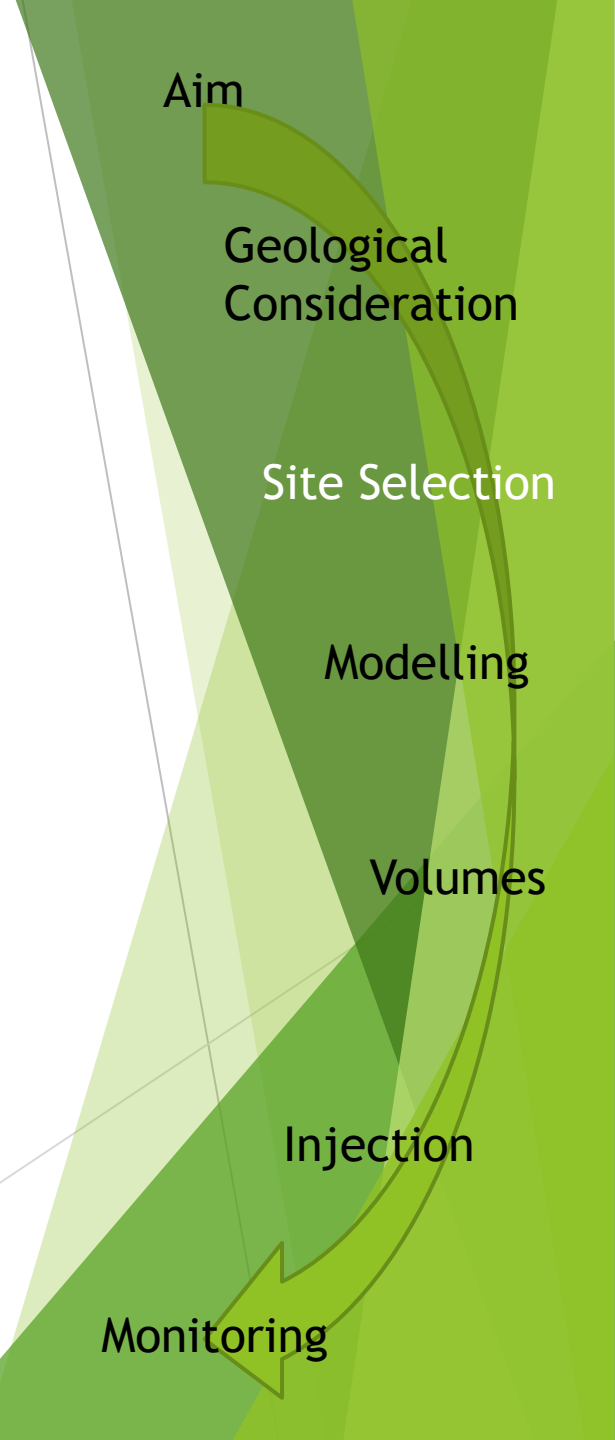

## ▶ Aquifers

### ▶ Pros

- ▶ No well integrity issues
- ▶ No volume issues for large aquifers

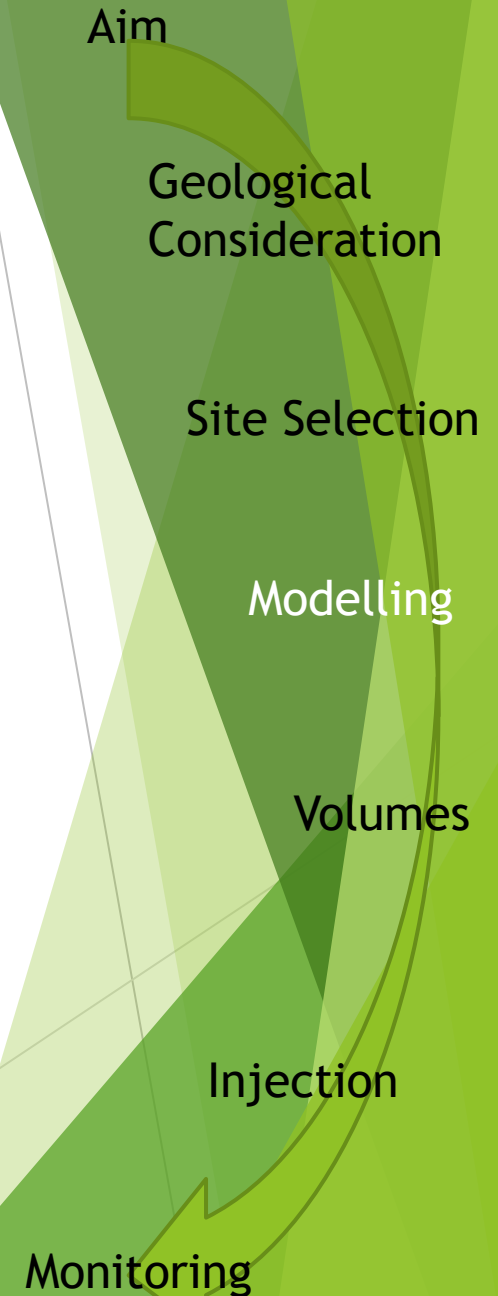

### ▶ Cons

- ▶ Geological uncertainties
- ▶ Faults and fractures
- ▶ Cap rock integrity
- ▶ Lack of high resolution seismic data

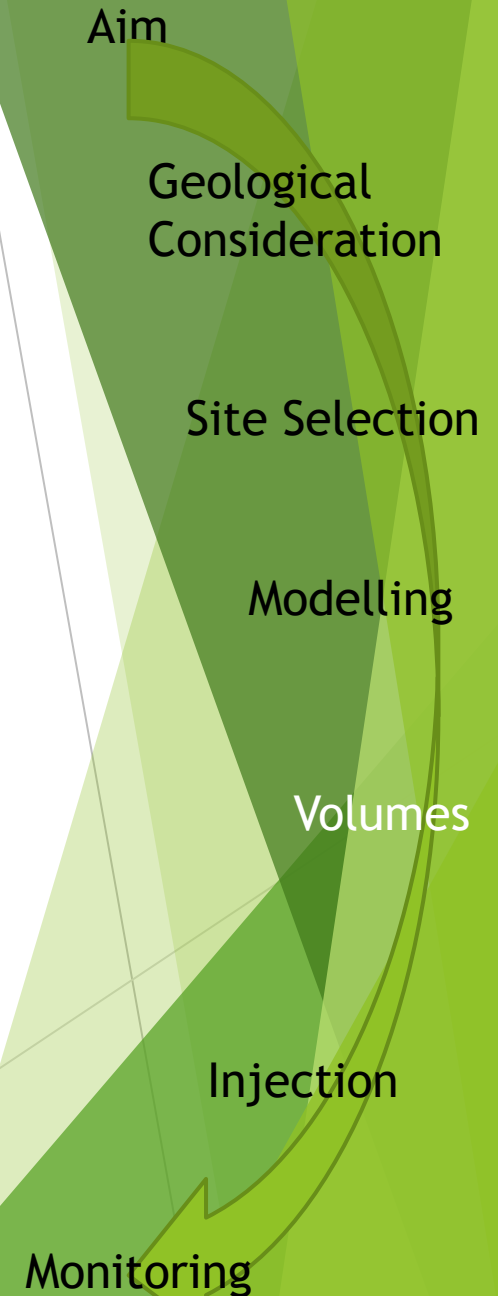

# Geological Modelling for CO<sub>2</sub> storage

- ▶ Static Modelling - similar to any static modelling workflow - Petrel/RMS etc
- ▶ Softwares for dynamic modelling
  - ▶ Eclipse 300, CMG (GEM)
  - ▶ MRST with CO<sub>2</sub> Lab Module
  - ▶ Stanford University code
  - ▶ GPU with parallel processing
- ▶ Key topics to be considered in modelling
  - ▶ Aquifers: Large size - many grid blocks
  - ▶ Depleted reservoirs: possible cross-flow in existing wells
  - ▶ CO<sub>2</sub> injection pressure - not to exceed frac gradient
  - ▶ SCAL/PVT properties - from lab measurements or analog reservoirs
  - ▶ Use of 3D seismic to understand structural elements
    - ▶ Seismic inversion for porosity modelling

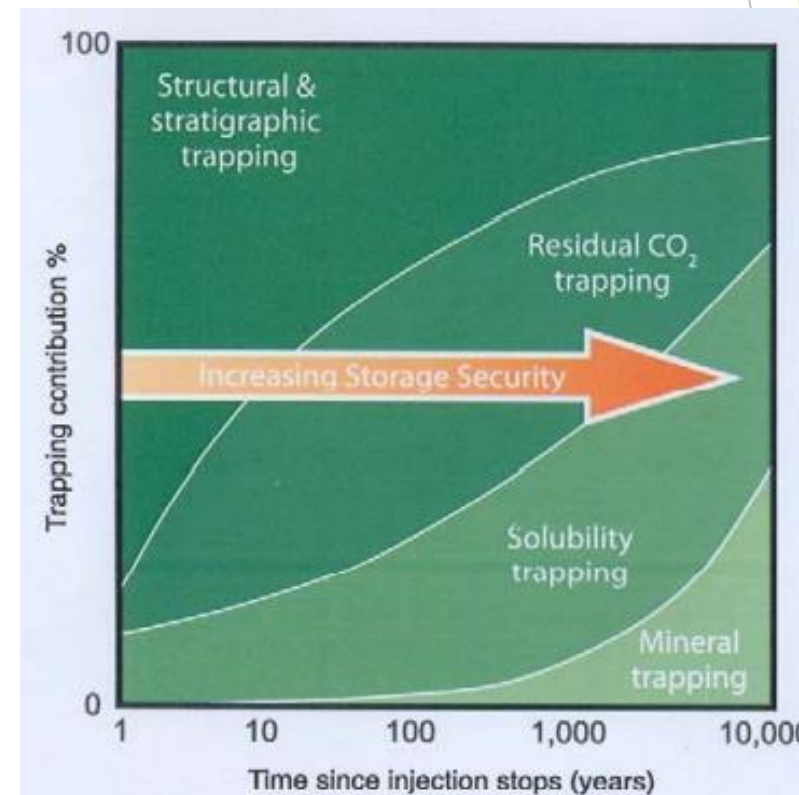

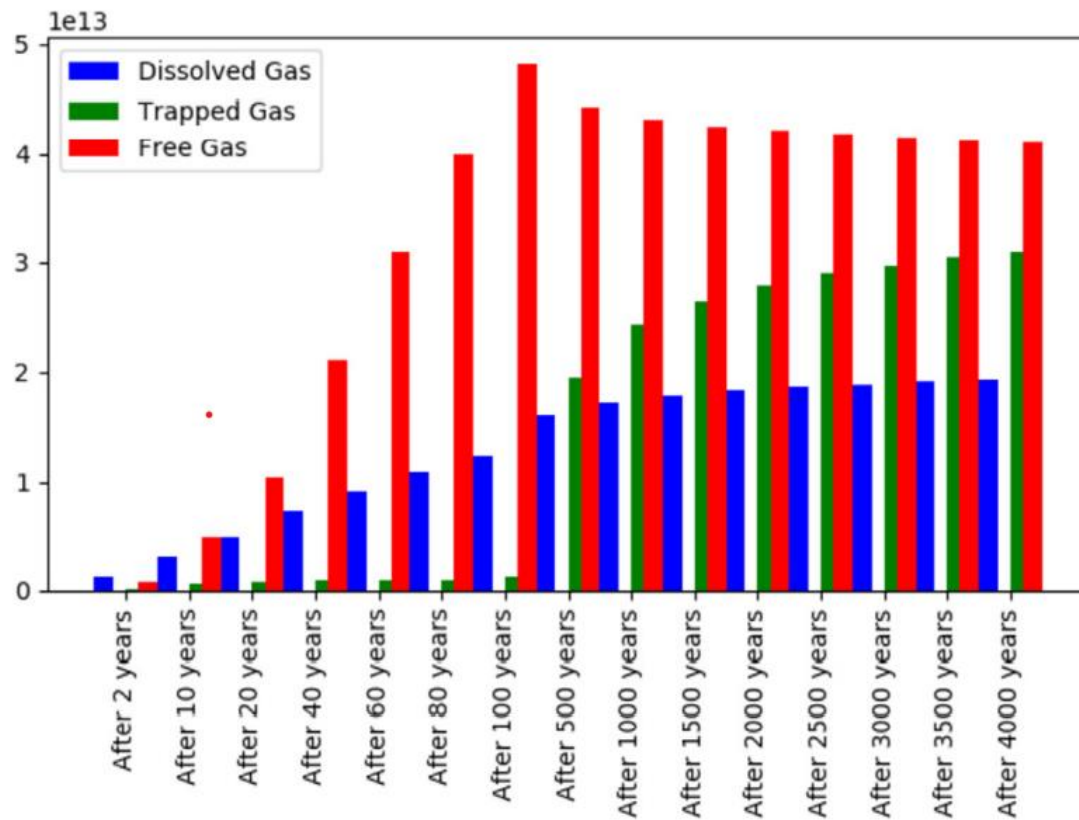

# Volumetrics for CO<sub>2</sub> storage

- ▶ **Static: Volumetric approach**
  - ▶ Aquifer with open boundaries
    - ▶ Pressure is not considered in this formulation
    - ▶ Considers only pore volume, density and capacity coefficient
      - ▶ Capacity coefficient: depends on trap heterogeneity, buoyancy of CO<sub>2</sub> and sweep efficiency
  - ▶  $M_{CO_2} = A \cdot h \cdot \Phi \cdot \rho \cdot (1 - S_{wirr}) \cdot C_c$
- ▶ **Static: Compressibility approach**
  - ▶ Aquifer with closed boundaries
  - ▶ pressure will be expected to increase in the aquifer during injection of CO<sub>2</sub>
  - ▶  $M_{CO_2} = (B_p + B_w) \cdot \rho \cdot V_p \cdot D_{pmax}$
- ▶ **Dynamic: Simulation**
- ▶ Volumetric capacities could be improved by the extraction of in-situ brine from the aquifers

Injection

Monitoring

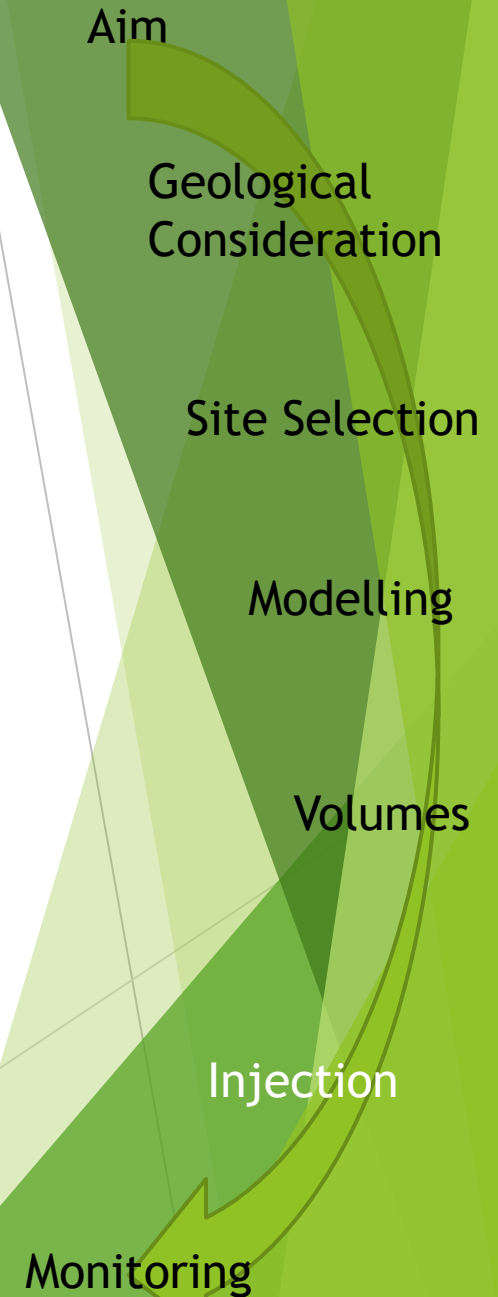

# CO2 Injection: Geomechanical Considerations

- ▶ Dry CO2 to be injected:
  - ▶ Permian Basin: supercritical dense phase (1900-2100 psi); just have booster pumps (much cheaper than compression).
  - ▶ Dry CO2 minimizes corrosion
  - ▶ Some operators get CO2 at ambient pressure (anthropogenic origin - CO2 captured) - need big compressors if reservoir pressures are high.
- ▶ 30F temperature drop expected by CO2 injection
  - ▶ Implications on well design; Thermal fracturing
- ▶ Injection pressures & geomechanical considerations:
  - ▶ Consider poro-elastic effects; Min horz stress ( $SH_{min}$ ) = frac gradient
  - ▶ Exceeding  $SH_{min}$  results in cap rock breach (SPE 108528)
  - ▶ Are faults and fractures at stable condition ?
  - ▶ If failure line is above Mohr Circle is stable

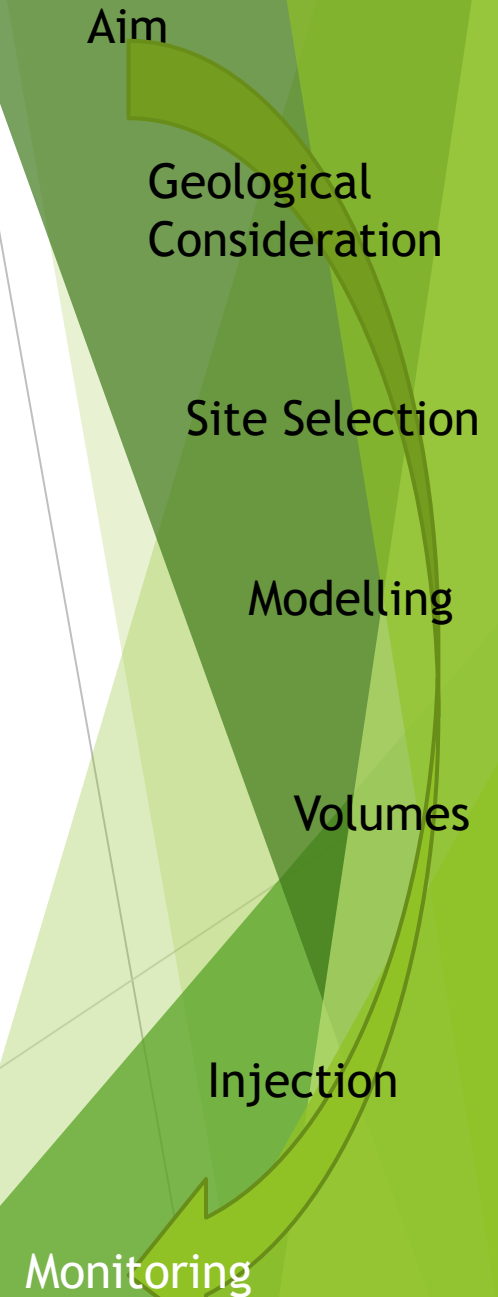

# CO2 Injection: Geochemical Considerations

- ▶ Geochemical considerations:
  - ▶ Rock dissolution and erosion under injection scenarios
  - ▶ PVT SIM NOVA software
  - ▶ CO2 is solid free, no erosion issues
- ▶ Cap rock geochemical considerations:
  - ▶ Calcite -> highest reaction rate
  - ▶ Experiments indicate 5% porosity becomes 5.0032% after CO2 injection
  - ▶ Experiments indicate 1% porosity becomes 1.0006% after CO2 injection
  - ▶ Each liter of water with CO2 is capable of dissolving 0.64 cc of rock
  - ▶ Geochemical integrity & monitoring

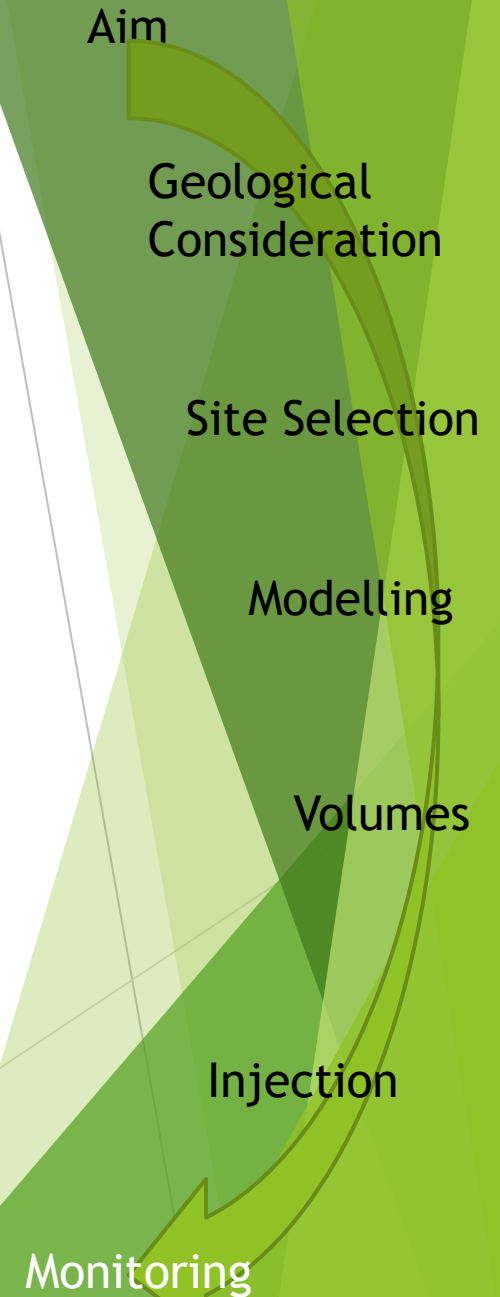

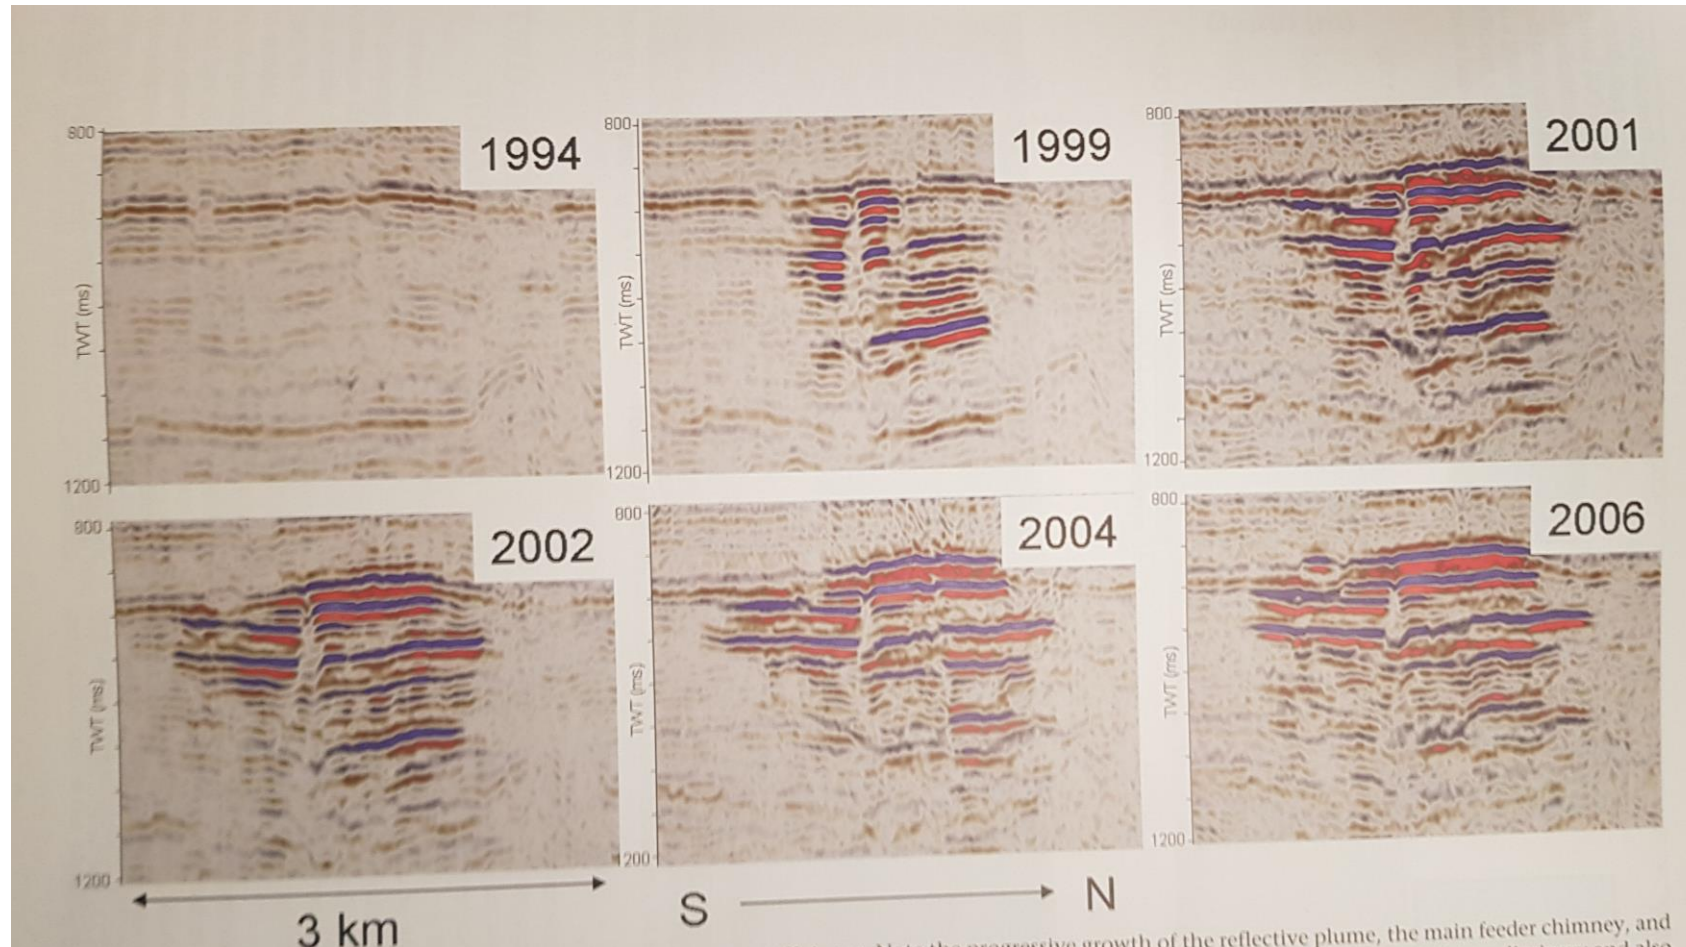

# Monitoring CO<sub>2</sub> storage - Example of Lacq TOTAL

- ▶ Monitoring wells to be located above and within the cap rock to monitor cap rock leakage
- ▶ CCS site in Lacq, 3.5 Km from Pau (France)
  - ▶ Buried geophones to minimize noise; capture small micro seismic events
  - ▶ Differentiate between real seismicity and CO<sub>2</sub> micro seismic activity
  - ▶ 7, 200 m shallow wells with 4 triaxial sensors each
  - ▶ SBA - Shallow Buried Array; 1 SBA per 4km<sup>2</sup> for fault monitoring
  - ▶ Deploy SBA 6 months prior to CO<sub>2</sub> injection
  - ▶ Deploy 1 deep borehole tool per injection well.
  - ▶ Geophones buried 30 years ago
  - ▶ CO<sub>2</sub> injection well at 4500 m TVD
- ▶ Other monitoring techniques: Gravimetry, time lapse seismic and resistivity, soil sampling, perfluorocarbons etc

# Monitoring CO<sub>2</sub> in Sleipner using time-lapse seismic
